(Received 19 June 2020; accepted 24 August 2020; published 17 September 2020)

This work provides the fundamental theoretical framework for molecular cavity quantum electrodynamics by resolving the gauge ambiguities between the Coulomb gauge and the dipole gauge Hamiltonians under the electronic state truncation. We conjecture that such ambiguity arises because not all operators are consistently constrained in the same truncated electronic subspace for both gauges. We resolve this ambiguity by constructing a unitary transformation operator that properly constrains all light-matter interaction terms in the same subspace. We further derive an equivalent and yet convenient expression for the Coulomb gauge Hamiltonian under the truncated subspace. We finally provide the analytical and numerical results of a model molecular system coupled to the cavity to demonstrate the validity of our theory.

DOI: 10.1103/PhysRevLett.125.123602

Coupling molecules to the quantized radiation field inside an optical cavity creates a set of new photon-matter hybrid excitations, so-called polaritons [1–4]. The rich dynamic interplay among these electronic, photonic, and nuclear degrees of freedom (d.o.f.) has enabled a new paradigm for achieving unique chemical reactivities [5–9]. The nonrelativistic quantum electrodynamics (QED) Hamiltonian that describes such quantum light-matter interactions should obey the gauge principle, i.e., giving rise to the same physical results (physical observables) upon a gauge transformation [10,11]. While the QED Hamiltonian under both the Coulomb gauge and the dipole gauge (length gauge) indeed obeys this principle, these Hamiltonians under a finite electronic state truncation (the few-level approximation) are known to give different results for physical observables [12–20], which is commonly referred to as the gauge ambiguity [14,17–19]. While using a finite level of projection on the dipole gauge Hamiltonian often provides accurate results of the polariton eigenspectrum (when the few-level truncation is a good approximation [18]) compared to the exact simulation, applying the same level of electronic state truncation \( H_C \) often leads to different results and, sometimes, a significant error in the ultrashort light-matter coupling regime [18–20]. In this Letter, we demonstrate that it is possible to resolve it and provide identical polariton eigenspectra from either the Coulomb or the dipole gauge Hamiltonian upon the same level of the electronic state truncation.

We begin by defining the matter Hamiltonian and the corresponding total dipole operator as follows:

\[
H_M = \hat{T} + \hat{V}(\hat{x}) = \sum_j \frac{1}{2m_j} \hat{p}_j^2 + \hat{V}(\hat{x}); \quad \hat{\mu} = \sum_j \hat{z}_j\hat{x}_j,
\]

where \( j \) is the index of the \( j \)-th charged particle (including all electrons and nuclei), with the corresponding mass \( m_j \) and charge \( z_j \). In addition, \( \hat{\mathbf{x}} \equiv \{ \hat{\mathbf{x}}_j \} = \{ \hat{\mathbf{R}}, \hat{\mathbf{r}} \} \) with \( \hat{\mathbf{R}} \) and \( \hat{\mathbf{r}} \) representing the nuclear and electronic coordinates, respectively, \( \hat{\mathbf{p}} \equiv \{ \hat{\mathbf{p}}_R, \hat{\mathbf{p}}_r \} = \{ \hat{\mathbf{p}}_j \} \) is the mechanical momentum operator as well as the canonical momentum operator, such that \( \hat{\mathbf{p}}_j = -i\hbar \nabla_j \). Further, \( \hat{T} = \hat{T}_R + \hat{T}_e \) is the kinetic energy operator, where \( \hat{T}_R \) and \( \hat{T}_e \) represent the kinetic energy operator for nuclei and for electrons, respectively, and \( \hat{V}(\hat{x}) \) is the potential operator that describes the Coulombic interactions among electrons and nuclei. The cavity photon field Hamiltonian under the single mode assumption is expressed as \( \hat{H}_{ph} = \hbar \omega_c (\hat{a}^\dagger \hat{a} + \frac{1}{2}) = \frac{1}{2} (\hat{\mathbf{p}}_c^2 + \omega_c^2 \hat{\mathbf{q}}_c^2) \), where \( \omega_c \) is the frequency of the mode in the cavity, \( \hat{a}^\dagger \) and \( \hat{a} \) are the photonic creation and annihilation operators, and \( \hat{q}_c = \sqrt{\hbar/2\omega_c} (\hat{a}^\dagger + \hat{a}) \) and \( \hat{p}_c = i\sqrt{\hbar/2\omega_c} (\hat{a}^\dagger - \hat{a}) \) are the photonic coordinate and momentum operators, respectively. Choosing the Coulomb gauge, \( \nabla \cdot \hat{\mathbf{A}} = \hat{\mathbf{A}} = 0 \), the vector potential becomes purely transverse \( \hat{\mathbf{A}} = \hat{\mathbf{A}}_t \). Under the long-wavelength approximation, \( \hat{\mathbf{A}} = \hat{A}_0 (\hat{a} + \hat{a}^\dagger) / 2 \), where \( \hat{A}_0 = \sqrt{\hbar/2\omega_c e_0} \hat{\mathbf{\varepsilon}} \), with \( \hat{\mathbf{\varepsilon}} \) as the quantization volume inside the cavity, \( e_0 \) as the permittivity, and \( \hat{\mathbf{\varepsilon}} \) is the unit vector of the field polarization.

The minimal coupling QED Hamiltonian in the Coulomb gauge (the “\( p \cdot A \)” form) is expressed as
\[ \hat{H}_C = \sum_j \frac{1}{2m_j} (\hat{p}_j - z_j \hat{A})^2 + \hat{V}(\hat{x}) + \hat{H}_{ph}, \]  

where \( \hat{p}_j = -i \hbar \nabla_j \) is the canonical momentum operator.

Upon a gauge transformation \( \hat{U}_x = \exp\{i/\hbar \sum_j z_j \chi(\hat{x}_j)\} \), \( \hat{H}_x = \hat{U}_x \hat{H}_C \hat{U}_x^\dagger \) remains gauge invariant, because \( \hat{H}_x = \sum_j (1/2m_j)(\hat{p}_j - z_j \hat{A}_j(\hat{x}_j))^2 + \hat{V}(\hat{x}) + \hat{H}_{ph}^x \), where \( \hat{A}_j(\hat{x}_j) = \hat{A} + \nabla \chi(\hat{x}_j) \) is gauge transformed vector potential that provides the same physical field, because \( \nabla_j \times \nabla \chi(\hat{x}_j) = 0 \). To prove the above equation, we have used \( e^{i\chi} \hat{O}(\hat{x})e^{-i\chi} = \hat{O}(\chi) \) for a unitary operator, as well as \( \hat{U}_x \hat{p}_j \hat{U}_x^\dagger = \hat{p}_j - z_j \nabla \chi(\hat{x}_j) \). Further, we have used \( \hat{U}_x \hat{H} \hat{U}_x^\dagger = \hat{V}(\hat{x}) \) because \( \hat{V} \) is a local potential operator for the matter, which is, only a function of \( \hat{x} \) and \( \hat{p} \) independent.

We further introduce the Power-Zienau-Woolley (PZW) gauge transformation operator [10,21] as

\[ \hat{U} = \exp\left[ -\frac{i}{\hbar} \hat{p} \cdot \hat{A} \right] = \exp\left[ -\frac{i}{\hbar} \hat{p} \cdot \hat{A}_0 (\hat{a} + \hat{a}^\dagger) \right]. \]

The PZW transformation operator can also be expressed as \( \hat{U} = \exp\{-i/\hbar \sqrt{2\omega_c/\hbar} \hat{p} \hat{A}_0 \} = \exp\{-i/\hbar [ \sum_j z_j \hat{A}_j ] \} \). Recall that a momentum boost operator \( \hat{U}_p = e^{i(i/\hbar) \hat{p} \cdot \hat{A}_0} \) displaces \( \hat{p} \) by the amount of \( p_0 \), such that \( \hat{U}_p \hat{O}(\hat{p}) \hat{U}_p^\dagger = \hat{O}(\hat{p} + p_0) \). Hence, \( \hat{U} \) is a boost operator for both the photon momentum \( \hat{p}_c \) by the amount of \( \sqrt{2\omega_c/\hbar} \hat{A}_0 \), as well as for the matter momentum \( \hat{p}_j \) by the amount of \( z_j \hat{A} \). The PZW gauge operator [Eq. (3)] is a special case of \( \hat{U}_x \), such that \( \chi = -\hat{x}_j \cdot \hat{A} \). Using \( \hat{U}_x^\dagger \) to boost the matter momentum, one can show that

\[ \hat{H}_C = \hat{U}_x^\dagger \hat{H}_M \hat{U}_x + \hat{H}_{ph}, \]

hence \( \hat{H}_C \) can be obtained [19] by a momentum boost with the amount of \( -z_j \hat{A} \) for \( \hat{p}_j \), then adding \( \hat{H}_{ph} \).

The QED Hamiltonian under the dipole gauge (the “d · E” form [21,22]) can be obtained by performing the PZW transformation on \( \hat{H}_M \) as follows:

\[ \hat{H}_D = \hat{U} \hat{H}_M \hat{U}^\dagger = \hat{U} \hat{U}_x^\dagger \hat{H}_M \hat{U}_x + \hat{U} \hat{H}_{ph} \hat{U}_x^\dagger \]

\[ = \hat{H}_M + \hbar \omega_c \left( \hat{a}^\dagger \hat{a} + \frac{1}{2} \right) + i \omega_c \hat{\mu} \hat{A}_0 (\hat{a}^\dagger - \hat{a}) + \frac{\omega_c}{\hbar} (\hat{\mu} \hat{A}_0)^2, \]

where we have used Eq. (4) to express \( \hat{H}_C \), and the last three terms of the above equation are the results of \( \hat{U} \hat{H}_{ph} \hat{U}_x^\dagger \). Using \( \hat{\xi}_c \) and \( \hat{p}_c \), one can instead show that \( \hat{H}_D = \hat{H}_M + \frac{i}{2} \omega_c \hat{\xi}_c^2 + \frac{1}{2} (\hat{p}_c + \sqrt{2\omega_c/\hbar} \hat{A}_0)^2 \), because the PZW operator boosts the photon momentum \( \hat{p}_c \) by \( \sqrt{2\omega_c/\hbar} \hat{A}_0 \).

When describing light-matter interactions, it is often necessary to truncate the electronic states for the matter (atoms or molecules), due to the difficulties of obtaining accurate high-lying electronic excited states. The gauge invariance is explicitly enforced between \( \hat{H}_C \) [Eq. (2)] and \( \hat{H}_D \) [Eq. (5)] through the unitary PZW gauge transformation [Eq. (3)] in the full Hilbert space. However, the gauge invariance could explicitly break down when a truncation of electronic states is applied to both Hamiltonians [18,19,23]. Consider a finite subset of states \( \{ | \alpha \rangle \} \), where the projection operator \( \hat{P} = \sum_\alpha | \alpha \rangle \langle \alpha | \) defines the truncation of the full electronic Hilbert space \( \hat{1}_r = \hat{P} + \hat{Q} \) to the corresponding subspace \( \hat{P} \). This truncation reduces the size of the Hilbert space from originally \( \hat{1}_r \otimes \hat{1}_R \otimes \hat{1}_{ph} \) to now \( \hat{P} \otimes \hat{1}_R \otimes \hat{1}_{ph} \), where \( \hat{1}_R \) and \( \hat{1}_{ph} \) represent the identity operators of the nuclear and the photonic d.o.f., respectively.

The truncated matter Hamiltonian is \( \hat{H}_M = \hat{P} \hat{H}_M \hat{P} = \hat{P} \hat{T} \hat{P} + \hat{P} \hat{V}(\hat{x}) \hat{P} \). Throughout this Letter, we use calligraphic symbols (such as \( \hat{P} \)) to indicate operators in the truncated Hilbert space. Truncating the momentum operator and dipole operator as \( \hat{P} \hat{p}_J \hat{P} \) and \( \hat{P} \hat{\mu} \hat{P} \), the QED Hamiltonians under the truncated subspace are defined [18] as

\[ \hat{H}'_C = \hat{H}_M + \hat{H}_{ph} + \sum_j \left( -\frac{z_j}{m_j} \hat{p}_j \hat{\mu} \hat{A}_0 (\hat{a}^\dagger - \hat{a}) + \frac{\omega_c}{\hbar} (\hat{\mu} \hat{A}_0)^2 \right). \]

\[ \hat{H}'_D = \hat{H}_M + \hat{H}_{ph} + i \omega_c \hat{\mu} \hat{P} \hat{A}_0 (\hat{a}^\dagger - \hat{a}) + \frac{\omega_c}{\hbar} (\hat{\mu} \hat{A}_0)^2. \]

Note that \( \hat{H}'_C = \hat{P} \hat{H}_C \hat{P} \) and \( \hat{H}'_D = \hat{P} \hat{H}_D \hat{P} \) do not generate the same polariton eigenspectrum [18–20,23] under the ultrastrong coupling regime [36]. Since electronic state truncation is often necessary, one would have to choose a particular gauge to describes light-matter interactions, leading to a well-known ambiguity [14,17,18] as to which Hamiltonian, \( \hat{H}'_C \) or \( \hat{H}'_D \), is viable to compute physical quantities when applying \( \hat{P} \). This fundamentally different behavior of \( \hat{H}'_C \) and \( \hat{H}'_D \) upon states truncation is also attributed to the fundamental asymmetry of \( \hat{\xi} \) and \( \hat{p} \) (when \( \hat{\xi} = \sum_j z_j \hat{A}_j \) operators) [18]. This ambiguity is attributed [18,25] to the fact that \( \hat{H}'_C \) usually requires a larger subset of the matter states to converge or generate consistent
results with $\hat{H}_D$, and apparently, under the complete basis limit, they should be gauge invariant. It will be theoretically novel to resolve this gauge ambiguity and provide consistent results from both gauges under the same level of electronic state truncation.

We conjecture that this gauge ambiguity emerges because the $\hat{P}\hat{U}$ and $\hat{U}\hat{P}$ in $\hat{H}_C$ [Eq. (6)] do not consistently constrain light-matter interaction operators in the same electronic subspace as those corresponding operators in $\hat{H}_D$. Indeed, all light-matter interaction operators in $\hat{H}_D$ are completely constrained in the subspace $\hat{P}$. Meanwhile, for $\hat{H}_C$, the corresponding light-matter interaction operators are not properly contained in $\hat{P}$, such that some of them are entering into the subspace $\hat{Q} = \hat{1}_r - \hat{P}$, and this is indeed the case for $\hat{U}\hat{P} = (\hat{P} + \hat{Q})\hat{U}\hat{P}$. It is also apparent by examining the diamagnetic term $\frac{e^2}{2m_j^2}\hat{A}^2$ in $\hat{H}_C$, which is effectively evaluated in the full space [18,19] $\hat{1}_r$ (based on the Thomas-Reiche-Kuhn sum rule), hence is not properly confined in $\hat{P}$. This diamagnetic term overestimates what it should be in the subspace [18,19], and by confining it inside $\hat{P}$, the results can be significantly improved [19]. Similarly, using $\hat{P}\hat{U}\hat{P}$ [19,23] does not resolve this gauge ambiguity either (see Supplemental Material [24], Sec. II).

Based on the above conjecture, the gauge ambiguity in the truncated electronic subspace will be resolved by defining the following unitary operator:

$$\hat{U} = \exp \left[ -\frac{i}{\hbar} \hat{P}\hat{\mu} \cdot \hat{A} \right] \equiv \exp \left[ -\frac{i}{\hbar} \hat{\mu}(\hat{x}, \hat{p}) \cdot \hat{A} \right], \tag{8}$$

such that all terms in $\hat{U} = \sum_{n=0}^{\infty} \frac{1}{n!} (-i/\hbar)^n (\hat{P}\hat{\mu} \hat{P})^n \hat{A}^n$ are properly confined within the subspace $\hat{P}$, and upon gauge transformation, all light-matter interaction operators are now consistently confined in $\hat{P}$ for both gauges. Here, $\hat{U}$ is defined analogously to the PZW gauge operator $\hat{U}$ in the full space [Eq. (3)], and $\hat{P}\hat{\mu} \hat{P} \equiv \hat{\mu}(\hat{x}, \hat{p})$ in principle is a function of both $\hat{x}$ and $\hat{p}$, due to the finite level projection that ruins the locality of $\hat{x}$ [19,37]. Further, $\hat{U}$ is a unitary transformation operator in the $\hat{P}$ subspace and the identity operator in the subspace of $\hat{1}_r - \hat{P}$, such that we still have $\hat{U}\hat{U}^\dagger = \hat{1}_r \otimes \hat{1}_r \otimes \hat{1}_\text{ph} = \hat{U}\hat{U}^\dagger$. Using $\hat{U}$, one can define the following Coulomb gauge Hamiltonian:

$$\hat{H}_C = \hat{U}^\dagger \hat{H}_M \hat{U} + \hat{H}_\text{ph}, \tag{9}$$

analogously to $\hat{H}_C$ in Eq. (4) in the full space. One can then formally show that $\hat{H}_C$ [Eq. (9)] and $\hat{H}_D$ [Eq. (7)] are related through $\hat{U}$ [Eq. (8)] as follows $\hat{U}\hat{H}_C \hat{U}^\dagger = \hat{H}_M + \hat{H}_\text{ph}\hat{U}^\dagger \hat{U} = \hat{H}_D$. Note that to establish the last equality, we have used the fact that $\hat{U}H_{\mu\mu} \hat{U}^\dagger = \hat{U}(\frac{1}{2}\omega_\mu^2 q_\mu^2 + \frac{1}{2}p_\mu^2) \hat{U}^\dagger = \frac{1}{2}\omega_\mu^2 q_\mu^2 + \frac{1}{2}(p_\mu + \sqrt{2}\omega_\mu/\hbar \hat{P}\hat{\mu} \hat{P} \Lambda_0)^2$.

Thus, we have formally demonstrated that the gauge ambiguities between the Coulomb and dipole gauge Hamiltonians can be resolved for an arbitrary matter-cavity hybrid system, under the same level of electronic state truncation.

To derive the detailed expression of $\hat{H}_C$, we notice that $\hat{P}\hat{\mu}\hat{P} \equiv \hat{\mu}(\hat{x}, \hat{p})$ is in principle a nonlinear function of both $\hat{x}$ and $\hat{p}$, as opposed to $\hat{\mu}$ [Eq. (1)] which is a pure linear function of $\hat{x}$. Thus, $\hat{U}^\dagger$ no longer just boosts the matter momentum by $z_j\hat{A}$. Using the Baker-Campbell-Hausdorff (BCH) identity, $\hat{U}^\dagger \hat{U} \hat{\mu} = \hat{\mu} + \frac{1}{2}(i/\hbar)\{\hat{\mu}, [\hat{P}, \hat{\mu}]\} + \cdots$, we have $\hat{U}^\dagger \hat{U} \hat{\mu} = \hat{\mu} - \hat{\nu}(\hat{x}, \hat{p}) + \hat{P}_j$, where $\hat{P}_j = \frac{1}{2}(i/\hbar)^2 \{\hat{\mu}, [\hat{P}, \hat{\mu}]\} + \cdots$ is the residual momentum that accounts for terms with more than one commutator in the BCH identity. Hence, under the projection, $\hat{U}^\dagger$ boosts the matter momentum by the amount of $-\hat{\nu}(\hat{x}, \hat{p}) + \hat{P}_j$.

Similarly, $\hat{U}^\dagger$ also displaces the matter coordinate as well as boost the matter momentum inside $\hat{V}(\hat{x}, \hat{p})$, whereas $\hat{U}^\dagger \hat{V} \hat{U}$ can be formally derived through the BCH identity.

Using the above result of $\hat{U}^\dagger \hat{U} \hat{\mu}$, as well as the fact that both $\hat{U}^\dagger$ and $\hat{U}$ commute with $\hat{P}$ such that $\hat{U}^\dagger \hat{U} \hat{P} \hat{U} \hat{U} = \hat{P} \hat{U}^\dagger \hat{U} \hat{P}$, we can derive $\hat{H}_C$ [in Eq. (9)] as

$$\hat{H}_C = \hat{U}^\dagger \hat{U} \hat{H}_M \hat{U} + \hat{U} \hat{\mu}(\hat{x}, \hat{p}) \hat{U} + \hat{H}_\text{ph} = \sum_j \frac{1}{2m_j} \hat{P}(\hat{p}_j - \hat{\nu}(\hat{x}, \hat{p}) + \hat{P}_j)^2 + \hat{U}^\dagger \hat{V}(\hat{x}, \hat{p}) \hat{U} + \hat{H}_\text{ph}, \tag{10}$$

where the sum $j$ includes all charged particles (electrons and nuclei). Note that $\hat{H}_C$ [Eq. (6)] as well as $\hat{H}_C$ [Eq. (2)] only contain the vector potential $\hat{A}$ up to the second order. This is no longer the case for $\hat{H}_C$ in Eq. (10). In fact, both the $\hat{P}_j$ term and the $\hat{U}^\dagger \hat{V}(\hat{x}, \hat{p}) \hat{U}$ term in principle contain infinite orders of $\hat{A}$. It is also self-evident that $\hat{H}_C$ [Eq. (10)] will return to $\hat{H}_C$ [Eq. (2)] under the complete electronic states limit, such that $\hat{\mu} = \hat{P}\hat{\mu} \hat{P} \rightarrow \hat{\mu}$, thus $\hat{V}(\hat{x}, \hat{p}) = \hat{V}(\hat{x}, \hat{p})$, hence $\hat{P}_j \rightarrow 0$, as well as $\hat{U} \rightarrow \hat{U}$, hence $\hat{U}^\dagger \hat{V}(\hat{x}) \hat{U} \rightarrow \hat{U}^\dagger \hat{V}(\hat{x}) \hat{U} = \hat{V}(\hat{x})$. Unfortunately, $\hat{H}_C$ no longer remains a gauge-invariant form (except when approaching the complete electronic states limit), by only involving charges but not higher multipole moments.

Nevertheless, $\hat{H}_C$ is invariant from $\hat{H}_D$ through the $\hat{U}$ transformation, resolving the ambiguity between them. There are scenarios where the Coulomb gauge is more convenient [25,38,39] than the dipole gauge for describing light-matter interactions, such as for a solid state material [25,38] interacting with the radiation field where the wave function satisfies periodic boundary conditions and the expectation value of the dipole operator becomes ill defined [40]. For these scenarios, instead of using $\hat{H}_C$, the currently derived $\hat{H}_C$ should be used to investigate the light-matter interactions. Compared to $\hat{H}_C$, which requires many

123602-3
To further present an equivalent yet convenient $\hat{H}_C$ for molecular cavity QED, we use the electronic states associated with the electronic Hamiltonian $\hat{H}_{el} = \hat{T}_r + \hat{V} = \hat{H}_M - \hat{T}_R$. The adiabatic electronic states $|\alpha(R)\rangle$ are the eigenstates of $\hat{H}_{el}$ through $\hat{H}_{el}|\alpha(R)\rangle = (\hat{T}_r + \hat{V})|\alpha(R)\rangle = E_\alpha(R)|\alpha(R)\rangle$. Using $\hat{P} = \sum_\alpha |\alpha(R)\rangle \langle \alpha(R)|$, the projected electronic Hamiltonian is $\hat{H}_{el} = \hat{P} \hat{H}_{el}^{\dagger} \hat{P} = \sum_\alpha E_\alpha(R) |\alpha(R)\rangle \langle \alpha(R)|$. Alternatively, diabatic electronic states $[41-44] \{ |\phi\rangle, |\psi\rangle \}$ can be obtained by the unitary transform $[41-45]$ from the adiabatic states $|\alpha(R)\rangle$. The character of the diabatic states does not depend on $R$, such that $\langle \psi | \nabla_R | \phi \rangle = 0$. With $\hat{P} = \sum_\alpha |\phi\rangle \langle \phi|$, $\hat{H}_{el} = \hat{P} \hat{H}_{el}^{\dagger} \hat{P} = \sum_\alpha V_{\phi\phi}(R) |\phi\rangle \langle \phi| + \sum_{\alpha \neq \phi} V_{\phi\alpha}(R) |\phi\rangle \langle \alpha|$, where $V_{\phi\phi}(R) = \langle \phi | H_{el} | \phi \rangle$ is a diabatic matrix element of $H_{el}$.

The central result of this Letter is reached by splitting the matter Hamiltonian as $\hat{H}_M = \hat{T}_R + \hat{H}_{el}$, then through a similar derivation procedure to obtain the following:

$$\hat{H}_C = \hat{U}^d \hat{P} \hat{R} \hat{U} + \hat{U} \hat{P} \hat{H}_{el}(\hat{R}, \hat{x}) \hat{U}^d + \hat{H}_{ph},$$

$$= \sum_{j \in R} \frac{1}{2m_j} \hat{P}(\hat{j} - i \nabla_R \hat{A} + \hat{P}_j)^2 \hat{P} + \hat{U} \hat{H}_{el} \hat{U} + \hat{H}_{ph},$$

where the sum over $j$ only includes nuclei. In the above expression, we did not specify the choice of $\hat{P}$, which could be either adiabatic or diabatic. Under the limiting case when $A_0 = 0$ or $\mu \cdot \hat{A} = 0$, both the $-\nabla_R \mu \cdot \hat{A}$ and $\hat{P}$ terms become 0, and $\hat{U}^d = \hat{U} \rightarrow \hat{P} \otimes 1_R \otimes 1_{ph}$. Thus, under such a limit, $\hat{H}_C \rightarrow \hat{H}_M + \hat{H}_{ph}$, hence, the matter and the cavity becomes decoupled. When using adiabatic states for the truncation, one can show that $[42,46]$ $\hat{P}_j \hat{P} \hat{P}_j = (\hat{P}_j - ih \sum_{\alpha, \beta} d_{\alpha \beta}^{(j)} |\alpha\rangle \langle \beta|)^2$, where $d_{\alpha \beta}^{(j)} \equiv \langle \alpha | \nabla_R | \beta \rangle$ is the well-known derivative couplings. Besides these adiabatic derivative couplings, the light-matter interaction also induced additional “derivative”-type couplings, $-\nabla_R \mu \cdot \hat{A}$ and $\hat{P}_j$, regardless of the electronic representation used in constructing $\hat{P}$. When using the Mulliken-Hush diabatic states $[43,47]$ which are the eigenstates of the $\hat{P} \hat{P} \hat{P}$ operator, such that $\hat{P} \hat{P} \hat{P} |\alpha\rangle \equiv \sum_\beta \mu_{\alpha\beta} |\beta\rangle$, one can prove that $\hat{P}_j = 0$ for all nuclei. This is because that $\nabla_R \mu \cdot \hat{A} = \sum_\beta \nabla_R \mu_{\alpha\beta} |\beta\rangle$, thus both $\hat{P}_j \hat{A}$ and $\hat{P}_j \hat{A}$, $\hat{P}_j$ become purely diagonal matrices, hence all of the higher order commutators in $\hat{U} \hat{P}_j \hat{U}$ become zero, resulting in $\hat{P}_j = 0$ for $j \in \mathbf{R}$.

Finally, we use the above general principle to derive analytical results for a model system. Without losing generality, let us consider a molecular system within the diabatic states $\{0\}, \{1\}$, which represents a broad range of chemical systems $[48-50]$. To simplify our algebra, we will assume there is only one nuclear d.o.f. with the coordinate $\hat{R}$ and momentum $\hat{p}_R$, and $\mu$ is always aligned along the polarization direction of $\hat{A}$ (which is $\hat{e}$). Under the truncated space, $\hat{P} = |0\rangle \langle 0| + |1\rangle \langle 1|$, the dipole operator is expressed as $\hat{\mu} \equiv \hat{P} \hat{\mu} \hat{P} = \Delta \mu \hat{\sigma}_z + \mu \hat{P} \mu_{\phi\phi} \hat{\sigma}_z$, where $\Delta \mu = 1/2(\mu_{00} - \mu_{11})$, $\mu = 1/2(\mu_{01} + \mu_{10})$, and $\mu_{\phi\phi}(\hat{R}) = \langle \phi | \hat{\mu} | \phi \rangle$. Note that these transition and permanent dipoles are functions of $\hat{R}$. The electronic Hamiltonian in this truncated subspace is $\hat{H}_{el} = \hat{P} \hat{H}_{el} \hat{P} = \epsilon(\hat{R}) \hat{P} + V_{10}(\hat{R}) \hat{R}_{\hat{R}}$, where $\epsilon(\hat{R}) = 1/2[|\nu_{00}(\hat{R})| - |\nu_{11}(\hat{R})|]$, $V_{10}(\hat{R}) = 1/2[|\nu_{00}(\hat{R})| + |\nu_{11}(\hat{R})|]$, and $\nu_{\phi\phi}(\hat{R}) = \langle \phi | \hat{H}_{el} | \phi \rangle$ (i.e., they are $H_{el}$'s matrix elements). Using the above spin representation for $\hat{\mu}$ and $\hat{H}_{el}$, as well as the BCH identity, one can analytically show (see Supplemental Material [24], Sec. I) that for the terms in $\hat{H}_C$ from Eq. (11), we have

$$\hat{U}^d \hat{P} \hat{R} \hat{U} = \hat{H}_d + [\epsilon(\hat{R}) \sin \theta - V_{10}(\hat{R}) \cos \theta] \{ \sin[\xi(\hat{A})] \hat{\sigma}_y + \cos \theta(1 - \cos[\xi(\hat{A})]) \hat{\sigma}_x + \sin \theta(\cos[\xi(\hat{A})] - 1) \hat{\sigma}_z \},$$

$$\xi = \sqrt{(\mu_{00} - \mu_{11})^2 - 4(\mu_{01} - \mu_{10})^2}, \tan \theta = 2(\mu_{01}/(\mu_{00} - \mu_{11})),$$ and the residual momentum is $\hat{P}_R = (1/2) \nabla_R \tan \theta \cos^2 \theta \{ (1 - \cos[\xi(\hat{A})]) \hat{\sigma}_y + [\sin \theta \hat{\sigma}_x - \cos \theta \hat{\sigma}_z] (\sin[\xi(\hat{A})] - \xi(\hat{A})) \}$. Note that for using diabatic states projection $\hat{P} \equiv \sum_\alpha |\alpha(R)\rangle \langle \alpha(R)|$, the $\hat{U}^d \hat{P} \hat{R} \hat{U}$ expression in Eq. (12) remains the same form with $\nu_{0i} = 0$, and so does the form of $\hat{H}_C$, except for the detailed expression of $\hat{P}$. The above result has two interesting limits. The first limit is the Rabi model (two-level atom interacts with a cavity) under the Coulomb gauge $[19]$ that provides the consistent results of the dipole gauge Rabi model (see Supplemental Material [24], Sec. I). The second limit is when these diabatic states are also Mulliken-Hush diabatic states, which means that $\mu_{10} = 0$ and $\tan \theta(\hat{R}) = 0$, hence $\nabla_R \tan \theta(\hat{R}) = 0$, and $\hat{P}_R = 0$, agreeing with our previous analysis of this residual momentum.

Figure 1 demonstrates the validity of our theory with a numerical example of a molecule couple to the cavity $[1]$. Here, we use the Shin-Metiu model molecular system $[26]$, which contains two fixed ions, one moving electron and proton (whose position is $\hat{R}$), all interacting with each other through modified Coulomb potentials. The details of this model, as well as the procedure to obtain the strict diabatic states (not the Mulliken-Hush diabatic representation) are provided in Supplemental Material, Secs. V–VII. Figure 1(a) presents the diabatic potential and the matrix elements of $\hat{\mu}$. Here, we focus on comparing the polaritonic potential energy surface $E_k(\hat{R})$, which is defined as $E_k = \hat{H}_{pl}(\hat{R}) - \hat{H}_{pl}(\hat{R})$, where $\hat{H}_{pl} = \hat{H}_p - \hat{T}_R$ represents the polariton Hamiltonian under the dipole gauge. In the truncated electronic subspace, $\hat{H}_{el}^{D} = \hat{H}_{el} + \hat{H}_{ph}$, $\hat{H}_{pl}^{D} = \hat{U}^d \hat{H}_{el}^{D} \hat{U}^d + \hat{H}_{ph}$, and $\hat{H}_{pl}^{C} = \hat{P}^{C} \hat{H}_{pl}^{D} \hat{P}^{C}$. Note that the analytical results of $\hat{U}^d \hat{H}_{el}^{D} \hat{U}^d$ is expressed in
In conclusion, we lay out the fundamental theoretical framework for the molecular cavity QED by presenting the general procedure to obtain the Coulomb gauge Hamiltonian that provide the consistent results from the dipole gauge Hamiltonian, under the same level of electronic state truncation. While using a finite level of projection on \( \hat{H}_D \) often provides accurate results of the polariton eigenspectrum, \( \hat{H}_C \) often introduce the gauge ambiguity (especially in the ultrastrong coupling regime). Instead, \( \hat{H}_C \) in Eq. (11) resolves such gauge ambiguity by proving consistent results as \( \hat{H}_D \). Investigations based upon the Coulomb gauge \([25,38,39]\) should consider using \( \hat{H}_C \).

FIG. 1. Shin-Metiu model (transferring proton and electron between two fixed ions) coupled to an optical cavity. (a) Diabatic potentials \( \mathcal{V}_{\text{dip}}(R) \) (upper panel) and dipole \( \mu \) (lower panel), with the inset describes characters of the diabatic states. (b) Polariton resonance at \( R = 0 \) and \( \hbar \omega_c = 3 \) eV, from \( \hat{H}_D^\text{pl} \) (solid), \( \hat{H}_C^\text{pl} \) (dotted), and \( \hat{H}_C^\text{pl} \) (dashed). The polariton eigenenergies as a function of the field strength \( \omega_c \) and \( R = 0 \) (resonance condition) and \( R = -1.74 \) a.u. (detuned), respectively. Again, the results from the Coulomb gauge and dipole gauge agree with each other exactly throughout the entire range of the field strength, whereas simple state truncation on the Coulomb gauge QED Hamiltonian breaks the gauge invariance, especially in the ultrastrong coupling regime \([19,36]\). Interestingly, \( \hat{H}_C \) requires much fewer vacuum’s Fock states to converge the polariton eigenspectrum \([25]\) compared to \( \hat{H}_D \), as shown in the SI. Hence, using \( \hat{H}_C \) for ultrastrong light-matter interactions provides a numerical advantage of using a much fewer Fock states to converge the polariton eigenspectrum, while uses as few matter states as required in \( \hat{H}_D \) (as opposed to \( \hat{H}_C \) which requires many electronic states \([18,25]\)).
